Overview of this manual

About this manual

This manual contains information about the RobotWare optionsMultiMove Independent and MultiMove Coordinated. The latter includes some extended functionality. Unless something else is specified, MultiMove refers to both these options.

Usage

This manual can be used either as a brief description to find out if MultiMove is the right choice for solving a problem, or as a description of how to use it. This manual provides information about system parameters and RAPID components related to MultiMove, and many examples of how to use them. The details regarding syntax for RAPID components, and similar, are not described here, but can be found in the respective reference manual.

Who should read this manual?

This manual is mainly intended for robot programmers.

Prerequisites

The reader should...

- · be familiar with industrial robots and their terminology.
- be familiar with the RAPID programming language.
- · be familiar with system parameters and how to configure them.
- be familiar with the option Multitasking (see Application manual Engineering tools).

Revision	Description
-	Released with RobotWare 6.0.
A	Released with RobotWare 6.01. • Added information about the Ethernet switch, see <i>Ethernet connections on page 21</i> .
В	Released with RobotWare 6.02. Section <i>Create a MultiMove system on page 27</i> updated to use Installation Manager.

Product documentation, IRC5

Categories for user documentation from ABB Robotics

The user documentation from ABB Robotics is divided into a number of categories. This listing is based on the type of information in the documents, regardless of whether the products are standard or optional.

All documents listed can be ordered from ABB on a DVD. The documents listed are valid for IRC5 robot systems.

Product manuals

Manipulators, controllers, DressPack/SpotPack, and most other hardware is delivered with a **Product manual** that generally contains:

- · Safety information.
- Installation and commissioning (descriptions of mechanical installation or electrical connections).
- Maintenance (descriptions of all required preventive maintenance procedures including intervals and expected life time of parts).
- Repair (descriptions of all recommended repair procedures including spare parts).
- · Calibration.
- Decommissioning.
- Reference information (safety standards, unit conversions, screw joints, lists of tools).
- Spare parts list with exploded views (or references to separate spare parts lists).
- Circuit diagrams (or references to circuit diagrams).

Technical reference manuals

The technical reference manuals describe reference information for robotics products.

- *Technical reference manual Lubrication in gearboxes*: Description of types and volumes of lubrication for the manipulator gearboxes.
- *Technical reference manual RAPID overview*: An overview of the RAPID programming language.
- Technical reference manual RAPID Instructions, Functions and Data types: Description and syntax for all RAPID instructions, functions, and data types.
- *Technical reference manual RAPID kernel*: A formal description of the RAPID programming language.
- *Technical reference manual System parameters*: Description of system parameters and configuration workflows.

Continues on next page

Continued

Application manuals

Specific applications (for example software or hardware options) are described in **Application manuals**. An application manual can describe one or several applications.

An application manual generally contains information about:

- The purpose of the application (what it does and when it is useful).
- What is included (for example cables, I/O boards, RAPID instructions, system parameters, DVD with PC software).
- · How to install included or required hardware.
- How to use the application.
- · Examples of how to use the application.

Operating manuals

The operating manuals describe hands-on handling of the products. The manuals are aimed at those having first-hand operational contact with the product, that is production cell operators, programmers, and trouble shooters.

The group of manuals includes (among others):

- · Operating manual Emergency safety information
- · Operating manual General safety information
- Operating manual Getting started, IRC5 and RobotStudio
- · Operating manual Introduction to RAPID
- · Operating manual IRC5 with FlexPendant
- · Operating manual RobotStudio
- Operating manual Trouble shooting IRC5, for the controller and manipulator.

Safety

Safety of personnel

A robot is heavy and extremely powerful regardless of its speed. A pause or long stop in movement can be followed by a fast hazardous movement. Even if a pattern of movement is predicted, a change in operation can be triggered by an external signal resulting in an unexpected movement.

Therefore, it is important that all safety regulations are followed when entering safeguarded space.

Safety regulations

Before beginning work with the robot, make sure you are familiar with the safety regulations described in the manual *Operating manual - General safety information*.

1 Introduction

1.1 About MultiMove

Purpose

The purpose of MultiMove is to let one controller handle several robots. This does not only save on hardware costs, it also allows advanced coordination between different robots and other mechanical units.

Here are some examples of applications:

- · Several robots can work on the same moving work object.
- · One robot can move a work object while other robots work on it.
- Several robots can cooperate to lift heavy objects.

Included functionality

MultiMove allows up to 6 tasks to be motion tasks (task that has move instructions). Since no more than 4 drive modules can be used, a controller can handle up to 4 robots. However, additional axes can be handled by separate tasks up to a total of 6 motion tasks.

Both MultiMove options allow you to implement:

- Independent movements (see Independent movements on page 60)
- Semi coordinated movements (see Semi coordinated movements on page 63)

In addition to what is mentioned above, the option MultiMove Coordinated allows you to implement:

Coordinated synchronized movements (see Coordinated synchronized movements on page 71)

Included options

If you have MultiMove, you automatically have access to some options that are necessary in order to use MultiMove.

MultiMove always includes the option:

Multitasking

In addition to what is mentioned above, MultiMove Coordinated includes the option:

Multiple Axis Positioner

Basic approach

This is the general approach for setting up a MultiMove system.

- 1 Install hardware and software (see *Installation on page 19*).
- 2 Configure system parameters (see *Configuration on page 29*).
- 3 Calibrate coordinate systems (see *Calibration on page 41*).
- 4 Write RAPID program for each task (see *Programming on page 55*).

1.2 Terminology

1.2 Terminology

About these terms

Some words have a specific meaning when used in this manual. It is important to understand exactly what is meant by these words. This manual's definition of these words are listed below.

Term list

Term	Explanation
Coordination	A robot that is coordinated to a work object will follow the movements of that work object.
Synchronization	Movements that are simultaneous. Synchronization refers to a similarity in time, not in room coordinates.
Positioner	A mechanical unit without TCP, which can only handle joint movements. A positioner is a mechanical unit, with one or several axes, that holds and moves a work object.
Robot	A mechanical unit with TCP, which can be programmed in Cartesian coordinates (x, y and z).
Task program	The same as a program. It is just a way of specifying that it is a program for one specific task.

1.3.1 About the example applications

1.3 Example applications

1.3.1 About the example applications

Three consistent examples

In this manual there are many examples (for configuration, RAPID code etc.). Every example is created for one of three physical robot systems. These example robot system setups are called "UnsyncArc", "SyncArc" and "SyncSpot" and will help you understand what kind of robot system an example is made for. The examples are also consistent, i.e. the RAPID code example for "SyncSpot" is made for a robot system configured as the configuration example for "SyncSpot".

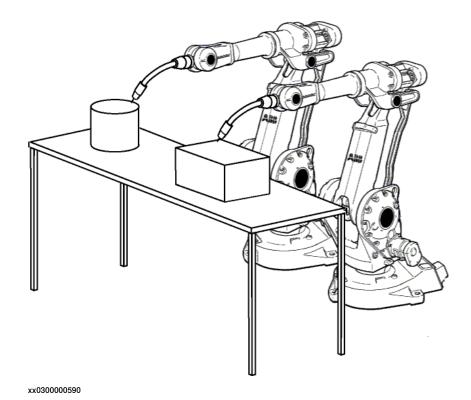

1.3.2 Example "UnsyncArc"

1.3.2 Example "UnsyncArc"

About example "UnsyncArc"

In this example, two robots work independently on one work piece for each robot. They do not cooperate in any way and do not have to wait for each other.

Illustration

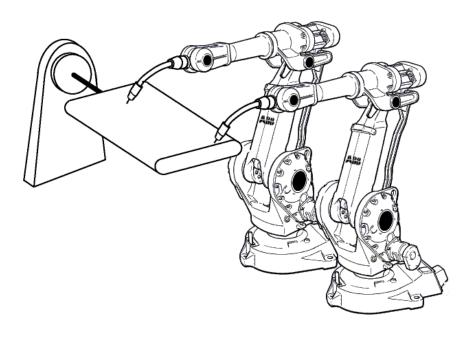

1.3.3 Example "SyncArc"

1.3.3 Example "SyncArc"

About example "SyncArc"

In this example, two robots perform arc welding on the same work piece. The work object is rotated by a positioner.

Illustration

xx0300000594

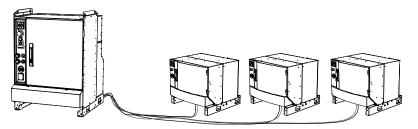

2 Installation

2.1 Hardware installation

2.1.1 About the hardware installation

Overview

A controller that handles several robots needs extra drive modules (one drive module per robot). Up to four drive modules can be used, including the one assembled with the control module.

xx0400001042

One Ethernet cable and one safety signal cable for each additional drive module must be connected to the control module. A MultiMove control module is equipped with an extra Ethernet switch to communicate with the additional drive modules.

This manual only describes what is specific for a MultiMove installation. For more information about installation and commissioning of the controller, see *Product manual - IRC5*.

2.1.2 Connections on the control module

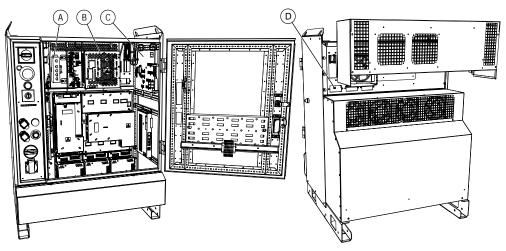

2.1.2 Connections on the control module

Connect drive modules to the control module

At delivery, both the Ethernet cable and the safety signal cable are connected to the drive module. They are also attached to a shield plate that fits in the slot of the control module.

Remove the cover from an empty slot and fit the shield plate of the communication cables in its place. Connect the Ethernet cable according to *Ethernet connections* on page 21 and safety signal cable according to *Safety signal connections* on page 23.

D	Ethernet card (only present if more than one drive module is used)
E	Panel board
F	Slots for inserting communication cables into the control cabinet

Ethernet connections

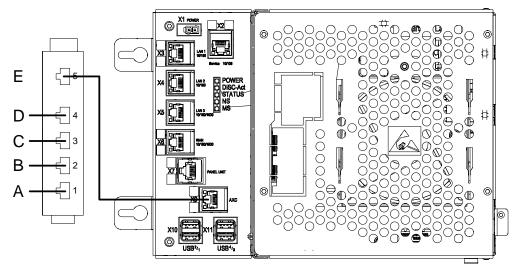

Connect the Ethernet cables according to the following figure:

Note

It is important that the right drive module is connected to the right Ethernet connection. If the order of the Ethernet connections do not match the selections made in Installation Manager (see *Create a MultiMove system on page 27*), the robot configuration will not correlate to the correct robot.

DSQC1000

xx1400000409

X17	Connector for safety signal cable to drive module #4

Remove the jumper connector and replace it with the safety signal cable.

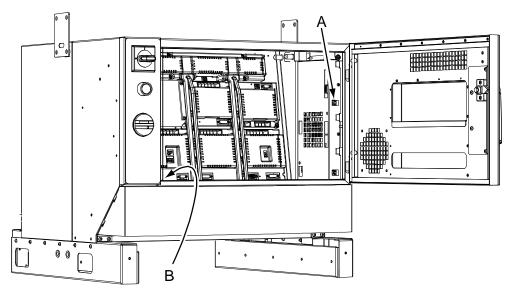

2.1.3 Connections on the drive module

2.1.3 Connections on the drive module

Already connected at delivery

When a MultiMove system is delivered from ABB, the Ethernet cable and the safety signal cable are already connected to the drive module. You only need to know how these cables are connected if you ar going to change the hardware configuration or replace parts.

Connect the cables from the control module

xx0600002787

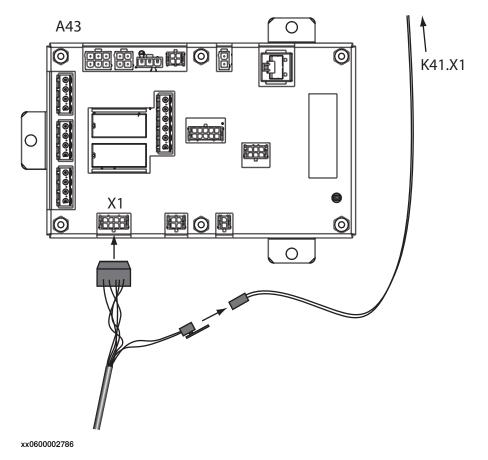

A	Ethernet connection
В	Contactor interface board

Connect the Ethernet cable to the Ethernet connection marked Computer module link. Connect the safety signal cable according to *Safety signal connection on page 26*.

2.1.3 Connections on the drive module *Continued*

Safety signal connection

The safety signal cable is connected to the Contactor interface board (A43), connector X1. There is also a connector that needs to be connected to a cable with a connector marked K41.X1.

2.2 Software installation

2.2.1 Software installation

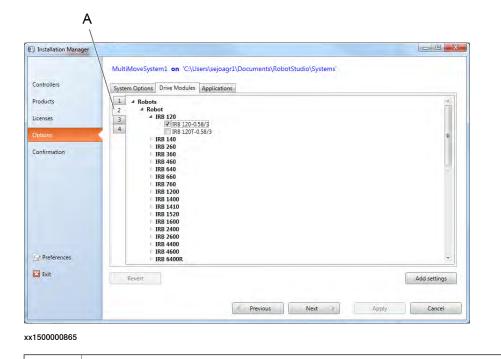

Install RobotStudio and RobotWare

Installation of RobotStudio and RobotWare on a PC is described in *Operating manual - Getting started, IRC5 and RobotStudio*.

Create a MultiMove system

Creating a new system is described in *Operating manual - RobotStudio*. Select the MultiMove option under **System Options**.

What is specific for a MultiMove system is that in the tab **Drive Modules**, one robot should be selected for each drive module.

Automatic configurations at installation

Α

When creating a system, some configurations are automatically set up according to information from your license. For each robot, the following are created:

- Tack
- · Mechanical Unit Group

One tab for each drive module

- Mechanical Unit
- Motion Planner

For more information about these system parameter types, see *System parameters on page 30*.

Continues on next page

2.2.1 Software installation *Continued*

CAUTION

A motion planner (type Motion Planner), created by the installation process, is configured to optimize the movement for its specific robot. If the default configuration is changed so that a robot uses the wrong motion planner, the robot motion will be affected.

3.1 Configuration overview

3 Configuration

3.1 Configuration overview

About the system parameters

This chapter contains a brief description of each parameter that is specific for MultiMove. Parameters that are used the same way as for a single robot system are not mentioned here.

For more information about system parameters, see *Technical reference* manual - System parameters.

About the examples

The first three examples cover the topics *Controller* and *Motion*, since these are related to the physical constellation of the robot system. The last example covers the topic *I/O System*, which is handled similarly regardless of the robot system.

3.2.1 Controller topic

3.2 System parameters

3.2.1 Controller topic

Task

These parameters belong to the type *Task* in the topic *Controller*:

Parameter	Description
Task	The name of the task.
	Note that the name of the task must be unique. This means that it cannot have the same name as the mechanical unit, and no variable in the RAPID program can have the same name.
Туре	Controls the start/stop and system restart behavior: NORMAL - The task program is manually started and stopped (e.g. from the FlexPendant). The task stops at emergency stop.
	 STATIC - At a restart the task program continues from where it was. The task program cannot be stopped from the FlexPendant or by emergency stop.
	 SEMISTATIC - The task program starts from the beginning at re- start. The task program cannot be stopped from the FlexPendant or by emergency stop.
	A task that controls a mechanical unit must be of the type NORMAL.
MotionTask	Indicates whether the task program can control a mechanical unit with RAPID move instructions.
Use Mechanical	Defines which mechanical unit group is used for the task.
Unit Group	Use Mechanical Unit Group refers to the parameter Name for the type Mechanical Unit Group.
	A motion task (<i>MotionTask</i> set to Yes) controls the mechanical units in the mechanical unit group. A non-motion task (<i>MotionTask</i> set to No) will still be able to read values (e.g. the TCP position) for the active mechanical units in the mechanical unit group.
	Note that <i>Use Mechanical Unit Group</i> must be defined for all tasks, even if the task does not control any mechanical unit.

Mechanical Unit Group

A mechanical unit group must contain at least one mechanical unit, robot or other mechanical unit (i.e. both *Robot* and *Mech Unit 1* cannot be left empty).

These parameters belong to the type Mechanical Unit Group in the topic Controller:

Parameter	Description	
Name	The name of the mechanical unit group.	
Robot	Specifies the robot (with TCP), if there is any, in the mechanical unit group. Robot refers to the parameter Name for the type Mechanical Unit in the topic Motion.	
Mech Unit 1	Specifies a mechanical unit without TCP, if there is any, in the mechanical unit group. Mech Unit 1 refers to the parameter Name for the type Mechanical Unit in the topic Motion.	
Mech Unit 2	Specifies the second mechanical unit without TCP, if there are more than one, in the mechanical unit group. Mech Unit 2 refers to the parameter Name for the type Mechanical Unit in the topic Motion.	

Continues on next page

3.2.1 Controller topic Continued

Parameter	Description
Mech Unit 3	Specifies the third mechanical unit without TCP, if there are more than two, in the mechanical unit group.
	<i>Mech Unit 3</i> refers to the parameter <i>Name</i> for the type <i>Mechanical Unit</i> in the topic <i>Motion</i> .
Mech Unit 4	Specifies the forth mechanical unit without TCP, if there are more than three, in the mechanical unit group.
	<i>Mech Unit 4</i> refers to the parameter <i>Name</i> for the type <i>Mechanical Unit</i> in the topic <i>Motion</i> .
Mech Unit 5	Specifies the fifth mechanical unit without TCP, if there are more than four, in the mechanical unit group.
	<i>Mech Unit 5</i> refers to the parameter <i>Name</i> for the type <i>Mechanical Unit</i> in the topic <i>Motion</i> .
Mech Unit 6	Specifies the sixth mechanical unit without TCP, if there are more than five, in the mechanical unit group.
	<i>Mech Unit 6</i> refers to the parameter <i>Name</i> for the type <i>Mechanical Unit</i> in the topic <i>Motion</i> .
Use Motion Planner	Defines which motion planner is used for calculating the movements of this mechanical unit group.
	Use Motion Planner refers to the parameter Name for the type Motion Planner in the topic Motion.

3.2.2 Motion topic

3.2.2 Motion topic

Drive Module User Data

If a drive module should be disconnected without disturbing robots and additional axes connected to other drive modules in the robot system, then use the Drive Module Disconnect function.

This parameter belongs to the type Drive Module User Data in the topic Motion.

Parameter	Description
	Set <i>Allow Drive Module Disconnect</i> to TRUE to disconnect the drive module.

Mechanical Unit

No parameters of type *Mechanical Unit* can be edited for a robot. They can only be edited for additional axes.

These parameters belong to the type *Mechanical Unit* in the topic *Motion*:

Parameter	Description	
Name	The name of the mechanical unit.	
Allow move of user frame	Indicates if the mechanical unit should be allowed to move user frames.	
Activate at Start Up	Indicates if the mechanical unit should be active when the controller starts up.	
	In a single robot system, the robot is always active. In a MultiMove system, any mechanical unit (including robots) can be inactive at start up and be activated later.	
Deactivation Forbidden	Indicates if it should be possible to deactivate the mechanical unit.	
	In a single robot system it is not possible to deactivate a robot. In a MultiMove system, one robot can be deactivated while another is still active.	

Motion Planner

A motion planner calculates the movements of a mechanical unit group. When several tasks are in synchronized movement mode they use the same motion planner (the first of the involved motion planners), see pictures in the following examples.

At installation a *Motion Planner* is set up for each robot. The *Motion Planner* is configured to optimize the motion for that specific robot. Do not change connection between robot and *Motion Planner*.

These parameters belong to the type *Motion Planner* in the topic *Motion*:

Parameter	Description
Name	The name of the motion planner.

Continues on next page

3.2.2 Motion topic Continued

Parameter	Description
Speed Control Warning	In synchronized movement mode, the speed of one robot can be slower than the programmed speed. This is because another robot might limit the speed (e.g. if the other robot has a longer path). If <i>Speed Control Warning</i> is set to Yes, a warning will be given when the robot moves slower than the programmed speed, in relation to the work object.
	Speed Control Warning is only used to supervise TCP speed, i.e. the speed of an additional axis is not supervised.
Speed Control Percent	If Speed Control Warning is set to Yes, a warning will be issued when the actual speed is slower than this percentage of the programmed speed.

3.2.3 I/O topic

3.2.3 I/O topic

Systems with several robots

Configuring *I/O* for a system with several robots is usually no different from a single robot system. However, for some system inputs and system outputs there is a need to specify which task or which robot it refers to. This is a description of the system parameters used to specify which task a system input is valid for, or which robot a system output is valid for. It is also explained when they have to be used. For more information, see *Technical reference manual - System parameters*.

System Input

These parameters belong to the type *System Input* in the topic *I/O*.

Parameter	Description
Argument 2	Specifies which task this system input should affect.
	If the parameter <i>Action</i> is set to <i>Interrupt</i> or <i>Load and Start</i> , then <i>Argument 2</i> must specify a task. All other values for <i>Action</i> results in a system input that is valid for all tasks, and <i>Argument 2</i> is not required.
	Argument 2 refers to the parameter Task for the type Task.

System Output

These parameters belong to the type System Output in the topic I/O.

Parameter	Description
Argument	Specifies which mechanical unit the system output refers to. If the parameter Status is set to TCP Speed, TCP Speed Reference or Mechanical Unit Active, then Argument must specify a mechanical unit. For all other values for Status the system output does not refer to a single robot, and Argument is not required. Argument refers to the parameter Name for the type Mechanical Unit in the topic Motion.

3.3.1 Configuration example for "UnsyncArc"

3.3 Configuration examples

3.3.1 Configuration example for "UnsyncArc"

About this example

This is an example of how to configure example "UnsyncArc", two independent robots. The robots are handled by one task each.

Task

Task	Туре	MotionTask	Use Mechanical Unit Group
T_ROB1	NORMAL	Yes	rob1
T_ROB2	NORMAL	Yes	rob2

Mechanical Unit Group

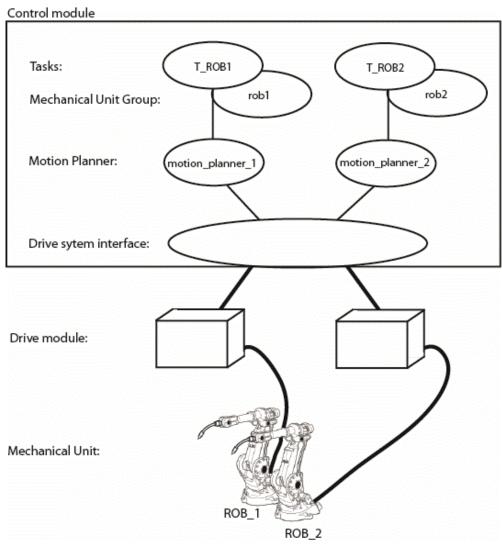

Name	Robot	Mech Unit 1	Use Motion Planner
rob1	ROB_1		motion_planner_1
rob2	ROB_2		motion_planner_2

Motion Planner

Name	Speed Control Warning
motion_planner_1	No
motion_planner_2	No

rob2	ROB_2		motion_planner_2
stn1		STN_1	motion_planner_3

Motion Planner

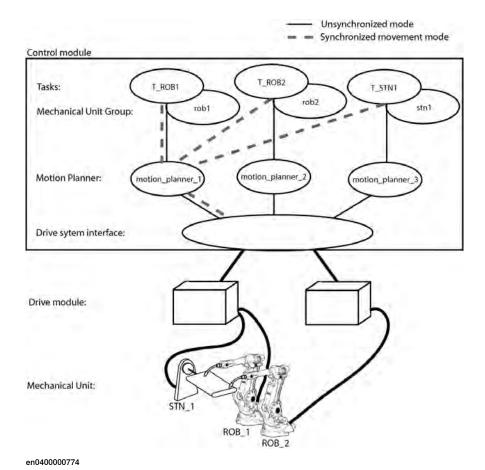

Name	Speed Control Warning	Speed Control Percent
motion_planner_1	Yes	90
motion_planner_2	Yes	90
motion_planner_3	No	

Mechanical Unit

Name	Allow move of user frame	Activate at Start Up	Deactivation Forbidden
ROB_1	Yes	Yes	Yes
ROB_2	Yes	Yes	Yes
STN_1	Yes	Yes	No

3.3.2 Configuration example for "SyncArc" *Continued*

Illustration

3.3.3 I/O configuration example

3.3.3 I/O configuration example

About this example

This is an example of how to configure some I/O signals that require an argument for task or robot. This example is based on the example "SyncArc".

The input signal $di_position$ is set up to interrupt the program execution and call the routine SetStartPosition in the task T_STN1. The output signal ao_speed1 is configured to indicate the speed of robot 1, and ao_speed2 to indicate the speed of robot 2.

System Input

Signal Name	Action	Argument	Argument 2
di_position	Interrupt	SetStartPosition	T_STN1

System Output

Status	Signal Name	Argument
TCP Speed	ao_speed1	ROB_1
TCP Speed	ao_speed2	ROB_2

4 Calibration

4.1 Calibration overview

Two types of calibration

There are two types of calibration that must be done for a robot system:

- 1 Joint calibration ensures that all axes are in correct position. Normally this is done before delivery of a new robot and only requires recalibration after repairing the robot. For more information, see the product manual for the respective robot.
- 2 Calibration of coordinate systems must be made when the robot is in place. A brief description of what coordinate systems to calibrate and in which order is presented below.

Calibrate coordinate systems

First of all you must decide what coordinate systems to use and how to place their origins and directions. For examples of suitable coordinate systems, see *Examples of coordinate systems on page 45*.

The coordinate systems are then calibrated in the following order:

	Action
1	Calibrate the tool. This includes calibration of TCP and load data. For description of how to calibrate the tool, see <i>Operating manual - IRC5 with FlexPendant</i> .
2	Calibrate the base coordinate system, relative to the world coordinate system, for all the robots. For description of how to calibrate the base coordinate system for a robot, see <i>Operating manual - IRC5 with FlexPendant</i> .
	If one robot already has a calibrated base coordinate system, the base coordinate system for another robot can be calibrated by letting the TCPs of the two robots meet at several points. This method is described in <i>Relative calibration on page 42</i> .
3	Calibrate the base coordinate systems, relative to the world coordinate system, for the positioners. For description of how to calibrate the base coordinate system for a positioner, see <i>Application manual - Additional axes and stand alone controller</i> .
4	Calibrate a user coordinate system, relative to the world coordinate system. For description of how to calibrate a user coordinate system, see <i>Operating manual - IRC5 with FlexPendant</i> .
5	Calibrate an object coordinate system, relative to the user coordinate system. For description of how to calibrate an object coordinate system, see <i>Operating manual - IRC5 with FlexPendant</i> .

4.2 Relative calibration

4.2 Relative calibration

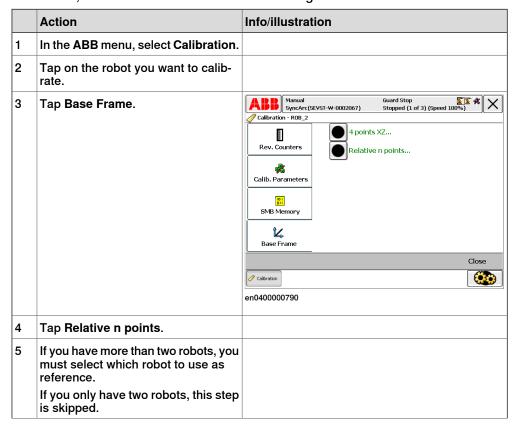

What is relative calibration

Relative calibration is used to calibrate the base coordinate system of one robot, using a robot that is already calibrated. This calibration method can only be used for a MultiMove system where two robots are placed close enough to have some part of their working areas in common.

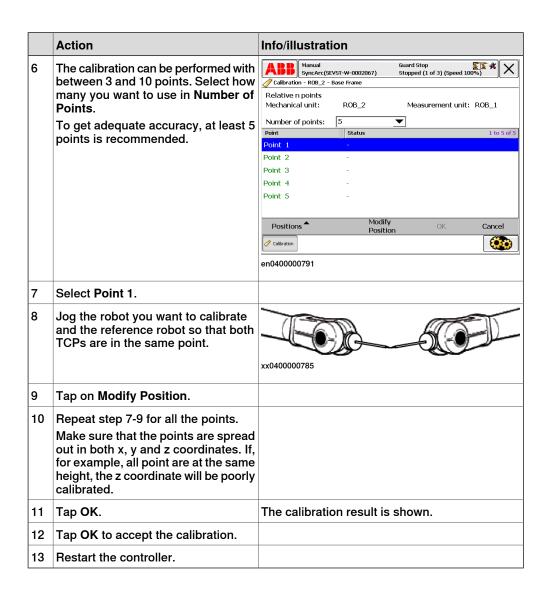

If one robot has a base coordinate system that is identical with the world coordinate system, this robot can be used as a reference for another robot. If no robot has a base coordinate system that is identical with the world coordinate system, the base coordinate system for one robot must be calibrated first. For information about other calibration methods, see *Operating manual - IRC5 with FlexPendant*.

How to perform relative calibration

The tools for both robots must be correctly calibrated before using relative calibration, and those tools must be active during calibration.

4.2 Relative calibration Continued

4.3 Calibration chains

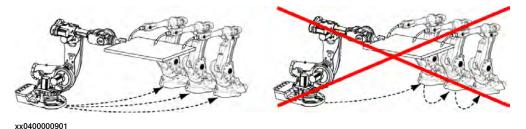

4.3 Calibration chains

Avoid long chains of calibrations

If a robot that is calibrated with relative calibration acts as reference in the next calibration, the inaccuracies in the calibrations are added for the last robot.

Example

You have four robots, where robot 1 holds a work piece that robots 2, 3 and 4 work on.

Calibrate robot 2, 3 and 4 against robot 1.

If you would use robot 1 as reference for robot 2, robot 2 as reference for robot 3 and robot 3 as reference for robot 4, the accuracy for robot 4 would be poor.

4.4.1 Example "UnsyncArc"

4.4 Examples of coordinate systems

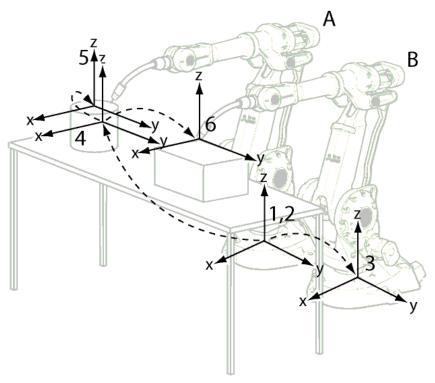

4.4.1 Example "UnsyncArc"

About this example

In this example, the world coordinate system and the base coordinate system for robot 1 (A) are identical.

The base coordinate system for robot 2 (B) is defined. Both robots have a user coordinate system with the origin in a table corner. An object coordinate system is defined for each robot's work object.

5 User interface specific for MultiMove

5.1 FlexPendant for MultiMove system

About FlexPendant for MultiMove system

Working with the FlexPendant in a MultiMove system is not very different from a single robot system. This chapter will explain a few things that are specific for a MultiMove system. For general information about the FlexPendant, see *Operating manual - IRC5 with FlexPendant*.

What is specific for MultiMove?

Some things that are specific for MultiMove are:

- The status bar shows which robots (and additional axes) are coordinated.
 See Status bar indications on page 48.
- When opening the program editor, you must select a task. See *Opening the Program Editor on page 50*.
- The Production window contains tabs for different tasks. See Production Window on page 51.
- The mechanical unit menu can contain several robots. See Mechanical unit menu on page 52.
- You can select which tasks to execute at start. See Select which tasks to start with START button on page 53.
- There is an additional method for calibrating a robot base frame, relative calibration. See Relative calibration on page 42.

5.2 Status bar indications

5.2 Status bar indications

Symbol descriptions

On the right side of the status bar, at the top of the FlexPendant, there are symbols for the mechanical units in the system.

Symbol	Description
xx0400001165	A robot that is not the selected mechanical unit, or coordinated with the selected mechanical unit. Jogging will not move this robot.
xx0400001166	A robot that is the selected mechanical unit, or coordinated with the selected mechanical unit. Jogging will move this robot (together with any other coordinated mechanical units).
xx0400001167	A robot belonging to an inactive task. For deactivation of tasks, see Select which tasks to start with START button on page 53.
xx0400001168	An additional axis that is not the selected mechanical unit, or coordinated with the selected mechanical unit. Jogging will not move this additional axis.
xx0400001169	An additional axis that is the selected mechanical unit, or coordinated with the selected mechanical unit. Jogging will move this additional axis (together with any other coordinated mechanical units).
xx0400001170	An additional axis that is not active. Either the mechanical unit is deactivated, or the task inactive.

Example

en0400001158

This is an example of a MultiMove system with 4 robots and 2 additional axes, where...

- · robot 1 belongs to a task that is inactive.
- robot 2 is not selected or coordinated with the selected unit (not affected by jogging).

5.2 Status bar indications *Continued*

- additional axis 1 is selected mechanical unit and robot 3 and 4 are coordinated with additional axis 1. Any jogging at this point will move these three mechanical units.
- additional axis 2 is deactivated, or its task inactive.

5.3 Opening the Program Editor

5.3 Opening the Program Editor

Select task

When opening the Program Editor for a system with more than one task, a list of all the tasks will be displayed. By tapping the task you want, the program code for that task is displayed.

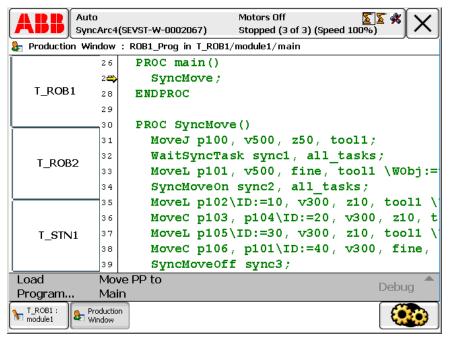

For a system with only one task, this list is never shown. The program code is shown directly.

5.4 Production Window

5.4 Production Window

The graphical display

In a system with more than one motion task there will be one tab for each motion task. By tapping a tab, you can see the program code for that task and where the program pointer and motion pointer are in that task.

en0400000796

Move program pointer

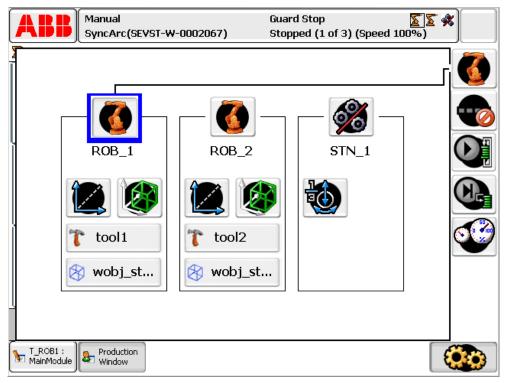

If you tap **Move PP To Main**, the program pointer will be moved to main for all motion task programs.

5.5 Mechanical unit menu

5.5 Mechanical unit menu

The graphical display

In the QuickSet menu, tap the Mechanical unit menu button. All mechanical units will be shown.

en0400000789

The selected mechanical unit is highlighted with a frame around it.

Any mechanical unit that is coordinated with the selected unit will be indicated with a flashing frame and the text Coord.

Jogging coordinated or uncoordinated

Jogging a mechanical unit will automatically move all units that are coordinated with it

In the example above, jogging STN_1 will move ROB_1 and ROB_2 as well, since they are coordinated with STN_1 (the work object wobj_stn1 is moved by STN_1). To be able to jog STN_1 without moving the robots, change the coordinate system for the robots to world coordinates or change the work object for the robots to wobj0. For more information about work objects being coordinated with a mechanical unit, see *Coordinated work objects on page 59*.

5.6 Select which tasks to start with START button

Background

The default behavior is that the programs of all NORMAL tasks are started simultaneously when pressing the START button. However, not all NORMAL task programs need to run at the same time. It is possible to select which of the NORMAL task programs will start when pressing the START button.

If **All Tasks** is selected in the **Task Panel Settings**, the programs of all STATIC and SEMISTATIC tasks with *TrustLevel* set to NoSafety can be selected to be started with the START button, forward stepped with the FWD button, backward stepped with the BWD button, and stopped with the STOP button.

If Task Panel Settings is set to Only Normal tasks, all STATIC and SEMISTATIC tasks are greyed out and cannot be selected in the task panel, Quickset menu (see Operating manual - IRC5 with FlexPendant, section Quickset menu). All STATIC and SEMISTATIC tasks will be started if the start button is pressed.

If **Task Panel Settings** is set to **All tasks**, STATIC and SEMISTATIC tasks with *TrustLevel*NoSafety can be selected in the task panel. All selected STATIC and SEMISTATIC tasks can be stopped, stepped, and started. .

A STATIC or SEMISTATIC task, not selected in the task panel, can still be executing. This is not possible for a NORMAL task.

Run Mode is always continuous for STATIC and SEMISTATIC tasks. The Run Mode setting in the Quickset menu is only applicable for NORMAL tasks (see *Operating manual - IRC5 with FlexPendant*, section *Quickset menu*).

This will only work in manual mode, no STATIC or SEMISTATIC task can be started, stepped, or stopped in auto mode.

Task Panel Settings

To start the **Task Panel Settings**, tap the ABB menu, and then **Control Panel**, **FlexPendant** and **Task Panel Settings**.

Selecting tasks

Use this procedure to select which of the tasks are to be started with the START button.

	Action
1	Set the controller to manual mode.
2	On the FlexPendant, tap the QuickSet button and then the tasks panel button to show all tasks.
	If Task Panel Settings is set to Only Normal tasks , all STATIC and SEMISTATIC tasks are greyed out and cannot be selected.
	If Task Panel Settings is set to All tasks , STATIC and SEMISTATIC tasks with <i>Trust-Level</i> NoSafety can be selected, while STATIC and SEMISTATIC tasks with TrustLevel set to other values are grayed out and cannot be selected.
3	Select the check boxes for the tasks whose program should be started by the START button.

5.6 Select which tasks to start with START button Continued

Resetting debug settings in manual mode

Use this procedure to resume normal execution manual mode.

	Action
1	Select Only Normal tasks in the Task Panel Settings.
2	Press START button. All STATIC and SEMISTATIC will run continuously and not be stopped by the STOP button or emergency stop.

Switching to auto mode

When switching to auto mode, all STATIC and SEMISTATIC tasks will be deselected from the tasks panel. The stopped STATIC and SEMISTATIC tasks will start next time any of the START, FWD or BWD button are pressed. These tasks will then run continuously forward and not be stopped by the STOP button or emergency stop.

What happens with NORMAL tasks that has been deselected in the tasks panel depends on the system parameter *Reset* in type *Auto Condition Reset* in topic *Controller*. If *Reset* is set to Yes, all NORMAL tasks will be selected in the tasks panel and be started with the START button. If *Reset* is set to No, only those NORMAL tasks selected in tasks panel will be started by the START button.

Note

Note that changing the value of the system parameter *Reset* will affect all the debug resettings (for example speed override and simulated I/O). For more information, see *Technical reference manual - System parameters*, section *Auto Condition Reset*.

Restarting the controller

If the controller is restarted, all NORMAL tasks will keep their status while all STATIC and SEMISTATIC tasks will be deselected from the tasks panel. As the controller starts up all STATIC and SEMISTATIC tasks will be started and then run continuously.

Deselect task in synchronized mode

If a task is in a synchronized mode, that is program pointer between SyncMoveOn and SyncMoveOff, the task can be deselected but not reselected. The task cannot be selected until the synchronization is terminated. If the execution continues, the synchronization will eventually be terminated for the other tasks, but not for the deselected task. The synchronization can be terminated for this task by moving the program pointer to main or to a routine.

If the system parameter *Reset* is set to Yes, any attempt to change to Auto mode will fail while a deselected task is in synchronized mode. Changing to Auto mode should make all NORMAL tasks selected, and when this is not possible it is not possible to change to Auto mode.

6 Programming

6.1 RAPID components

Data types

This is a brief description of each data type in MultiMove. For more information, see the respective data type in *Technical reference manual - RAPID Instructions*, *Functions and Data types*.

Data type	Description
syncident	A variable of the data type syncident is used to identify which WaitSyncTask, SyncMoveOn or SyncMoveOff instructions, in the different task programs, should be synchronized with each other.
	The name of the syncident variable must be the same in all task programs.
	Declare syncident variables globally in each task. Do not reuse a syncident variable (each WaitSyncTask, SyncMoveOn and SyncMoveOff in a task program should have a unique syncident).
tasks	A persistent variable of the data type tasks contains names of the tasks that will be synchronized with WaitSyncTask or SyncMoveOn.
	The tasks variable must be declared as system global (persistent) variable, with the same name and the same content in all task programs.
identno	A numeric value or a variable of type identno is used in the argument ID of any move instructions executed between the SyncMoveOn and SyncMoveOff instructions.

System data

System data is predefined, internal data of the robot. A system data can be read, but not changed, from a RAPID program. For more information, see *Technical reference manual - RAPID Instructions, Functions and Data types*.

System data	Description
ROB_ID	Reference to the robot (if any) controlled by the task. If used from a task that does not control a robot, an error will occur. Always use TaskRunRob() to check this before using ROB_ID.

Instructions

This is a brief description of each instruction in MultiMove. For more information, see the respective instruction in *Technical reference manual - RAPID Instructions, Functions and Data types*.

Instruction	Description
,	${\tt WaitSyncTask}$ is used to synchronize several task programs at a special point in the program.
	A WaitSyncTask instruction will wait for the other task programs. When all task programs have reached the WaitSyncTask instruction, they will continue their execution.

6.1 RAPID components

Continued

Instruction	Description
SyncMoveOn	SyncMoveOn is used to start synchronized movement mode.
	A SyncMoveOn instruction will wait for the other task programs. When all task programs have reached the SyncMoveOn, they will continue their execution in synchronized movement mode. The move instructions in the different task programs are executed simultaneously, until the instruction SyncMoveOff is executed.
	A stop point must be programmed before the SyncMoveOn instruction.
SyncMoveOff	SyncMoveOff is used to end synchronized movement mode.
	A SyncMoveOff instruction will wait for the other task programs. When all task programs have reached the SyncMoveOff, they will continue their execution in unsynchronized mode.
	A stop point must be programmed before the SyncMoveOff instruction.
SyncMoveUndo	SyncMoveUndo is used to turn off synchronized movements, even if not all the other task programs execute the SyncMoveUndo instruction.
	SyncMoveUndo is intended for UNDO handlers. When the program pointer is moved from the procedure, SyncMoveUndo is used to turn off the synchronization.
MoveExtJ	MoveExtJ (Move External Joints) moves one or several mechanical units without TCP.
	MoveExtJ is used to move additional axes, in a task without any robot.

Functions

This is a brief description of each function in MultiMove. For more information, see the respective function in *Technical reference manual - RAPID Instructions*, *Functions and Data types*.

Function	Description
IsSyncMoveOn	IsSyncMoveOn is used to tell if the mechanical unit group is in synchronized movement mode.
	A task that does not control any mechanical unit can find out if the mechanical units defined in the parameter <i>Use Mechanical Unit Group</i> are in synchronized movement mode.
RobName	RobName is used to get the name of the robot controlled by the task. It returns the mechanical unit name as a string. If called from a task that does not control a robot, an empty string is returned.

6.1 RAPID components Continued

Synchronizing argument

This is a brief description of the arguments used by move instructions to facilitate the synchronization between tasks. For more information, see any move instruction in *Technical reference manual - RAPID Instructions, Functions and Data types*.

Argument	Description
ID	All move instructions executed between the <code>SyncMoveOn</code> and <code>SyncMoveOff</code> instructions must have the argument <code>ID</code> specified. The <code>ID</code> argument must be the same for all the move instructions (in each task program) that should execute simultaneously.
	The ID argument can be a numeric value or a syncident variable.
	The purpose of ID is to support the operator by making it easier to see which move instructions that are synchronized with each other. Make sure an ID value is not used for more than one move instruction, between the same SyncMoveOn and SyncMoveOff instructions. It is also helpful for the operator if the ID values are ascending for consecutive move instructions (e.g. 10, 20, 30,).
	Move instructions that are not between the <code>SyncMoveOn</code> and <code>SyncMoveOff</code> instructions must not have the argument <code>ID</code> .

6.2 Tasks and programming techniques

6.2 Tasks and programming techniques

Different tasks

Each task program can handle the movements for one robot and up to 6 additional axes. Several tasks can be used, each containing a program quite similar to the program of the main task in a single robot application. For more information about the tasks, see the section about Multitasking in *Application manual - Controller software IRC5*.

One task program per robot

Each task program can only handle one TCP. This means that you must have one task for each robot.

Additional axes in separate tasks

Additional axes that move a work object can be handled by the same task program as one of the robots. However, if the additional axes should be able to move independent of the robots, it is best to let a separate task program handle the additional axes.

6.3 Coordinated work objects

6.3 Coordinated work objects

About work objects

This section will only describe how to make a work object coordinated with a mechanical unit. For a detailed description of work objects, see *wobjdata - Work object data* in *Technical reference manual - RAPID Instructions, Functions and Data types*.

What determines coordination?

When declaring a work object, the second attribute (ufprog) and the third attribute (ufmec) determine if the work object is coordinated to any mechanical unit.

robhold

robhold defines if the work object is held by the robot in this task.

robhold is normally set to FALSE. The task of the robot that holds the work object (where robhold would be set to TRUE) does not have to declare it unless a stationary tool is used.

ufprog

If the work object is stationary, ufprog is set to TRUE.

If the work object can be moved by any mechanical unit, ufprog is set to FALSE.

ufmec

ufmec is set to the name of the mechanical unit that moves the work object.

If ufprog is set to TRUE, ufmec can be left as an empty string (no mechanical unit can move the work object).

Example 1

This is an example of a work object that can be moved by a mechanical unit with the name STN_1:

```
PERS wobjdata wobj_stn1 := [FALSE, FALSE, "STN_1", [[0,0,0],[1,0,0,0]], [[0,0,250],[1,0,0,0]]];
```

Example 2

Robot ROB_1 is welding a part that is hold by robot ROB_2. The workobject is moved by robot ROB_2.

When declaring the work object in ROB_1, the robhold argument must be set to FALSE, since robhold TRUE is only used for stationary tools. For ROB_2, any work object can be active since it is only the joint angles of ROB_2 that coordinates the work object for ROB_1.

```
PERS wobjdata wobj_rob1 := [FALSE, FALSE, "ROB_2", [[0,0,0],[1,0,0,0]], [[0,0,250],[1,0,0,0]]);
```

6.4.1 About independent movements

6.4 Independent movements

6.4.1 About independent movements

What is independent movements

If the different task programs, and their robots, work independently, no synchronization or coordination is needed. Each task program is then written as if it was the program for a single robot system.

Other dependencies than movements

Sometimes, even if the movements do not need to be coordinated, the task programs can have dependencies. For example, if one robot leaves an object that a second robot will pick up, the first robot must finish with the object before the second robot can grab it.

These interactions can be solved with:

- the instruction WaitSyncTask
- I/O signals
- persistent variables together with WaitUntil

See the section about Multitasking in *Application manual - Controller software IRC5*.

6.4.2 Example "UnsyncArc" with independent movements

Program description

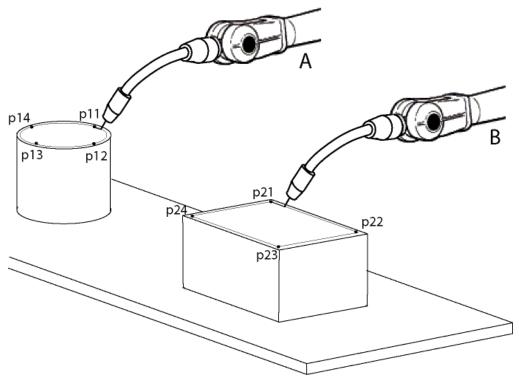

In this example, one robot welds a circle on one object while the other robot welds a square on another object.

Note

To make the example simple and general, ordinary move instructions (e.g. MoveL) are used instead of weld instructions (e.g. ArcL). For more information about arc welding, see *Application manual - Arc and Arc Sensor*.

6.5.1 About semi coordinated movements

6.5 Semi coordinated movements

6.5.1 About semi coordinated movements

What is semi coordinated movements

Several robots can work with the same work object, without synchronized movements, as long as the work object is not moving.

A positioner can move the work object when the robots are not coordinated to it, and the robots can be coordinated to the work object when it is not moving. Switching between moving the object and coordinating the robots is called semi coordinated movements.

Implementation

Semi coordinated movements require some synchronization between the task programs (e.g. a *WaitSyncTask* instruction). The positioner must know when the work object can be moved, and the robots must know when they can work on the work object. However, it is not required that every move instruction is synchronized.

Advantages

The advantage is that each robot can work independently with the work object. If the different robots perform very different assignments, this may save cycle time compared to letting all the robot movements be synchronized. 6.5.2 Example "SyncArc" with semi coordinated movements

6.5.2 Example "SyncArc" with semi coordinated movements

Program description

In this example, we want to accomplish the welding of a small square and a long line on one side of the object. On another side of the object we want to make a square and a circle.

The positioner will first position the work object with the first side up, while the robots wait. Robot 1 will then weld a line at the same time as robot 2 welds a square.

When the robots are done with the first welding operations, they wait while the positioner turns the work object so the second side is upwards. Robot 1 will then weld a circle at the same time as robot 2 welds a square.

WARNING

If the movement of the work object and the robot is not separated with WaitSyncTask and stop points the following can occur:

- · the mechanical units controlled by the different tasks can collide
- the robot is stepping backwards in the wrong direction
- the movement or restart instruction can be blocked.

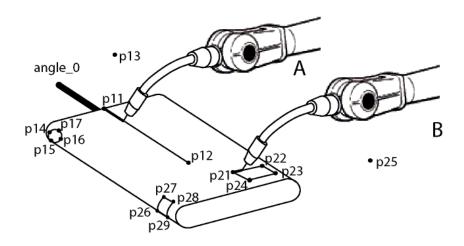

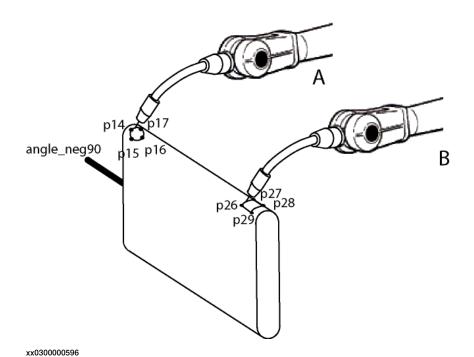

Note

To make the example simple and general, ordinary move instructions (e.g. MoveL) are used instead of weld instructions (e.g. ArcL). For more information about arc welding, see *Application manual - Arc and Arc Sensor*.

6.5.3 Considerations and limitations when using semi coordinated movements

Stand still in known position

The unit that controls the frame should stand still in a known position. To get a known position, order a movement to a finepoint.

Activate task

The unit that controls the frame should be activated in the task selection panel on the FlexPendant (see *Selecting tasks on page 53*).

Finepoints and WaitSyncTask before and after semi coordinated movement

The semi coordinated movement shall be separated with finepoints and WaitSyncTask instructions before and after the movement.

Dealing with a cleared path

When any of the instructions listed below is used, the path is removed and the position cannot be read by the other tasks.

- ActUnit
- DeactUnit
- ClearPath
- SyncMoveOn
- SyncMoveoff
- SyncMoveSuspend
- SyncMoveResume

After any of these instructions, order a movement to a wanted position for the unit that controls the frame and insert a WaitSyncTask instruction before the semicoordinated movement.

Before changing to synchronized movement with <code>SyncMoveOn</code> or <code>SyncMoveResume</code>, the semi coordinated movement must be ended with a finepoint and a <code>WaitSyncTask</code>.

Example with semi coordinated and coordinated movement

6.5.3 Considerations and limitations when using semi coordinated movements Continued

```
MoveL p1_90, v100, fine, tcp1 \WObj:= rob2_obj;
 WaitSyncTask sync1, task_list;
 SyncMoveOn sync2, task_list;
 MoveL p1_100 \ID:=10, v100, fine, tcp1 \WObj:= rob2_obj;
 SyncMoveOff sync3;
  !Wait until the movement has been finished in T_ROB2
 WaitSyncTask sync3, task_list;
  !Now a semicoordinated movement can be performed
 MoveL p1_120, v100, z10, tcp1 \WObj:= rob2_obj;
 MoveL p1_130, v100, fine, tcp1 \WObj:= rob2_obj;
 WaitSyncTask sync4, task_list;
ENDPROC
!Program example in task T_ROB2
PERS tasks task_list{2} := [ ["T_ROB1"], ["T_ROB2"] ];
VAR syncident sync0;
VAR syncident sync1;
VAR syncident sync2;
VAR syncident sync3;
VAR syncident sync4;
PROC main()
 MoveL p_fine, v1000, fine, tcp2;
 WaitSyncTask sync0, task_list;
  !Wait until the movement in T_ROB1 task is finished
 WaitSyncTask sync1, task_list;
 SyncMoveOn sync2, task_list;
 MoveL p2_100 \ID:=10, v100, fine, tcp2;
 SyncMoveOff sync3;
  !The path has been removed at SyncMoveOff
  !Perform a movement to wanted position for the object to make
       the position available for other tasks
 MoveL p2_100, v100, fine, tcp2;
 WaitSyncTask sync3, task_list;
 WaitSyncTask sync4, task_list;
 MoveL p2_110, v100, z10, tcp2;
  . . .
ENDPROC
```

When switching between semicoordinated to synchronized movement, a WaitSyncTask is needed (when using identity sync1).

When switching between synchronized to semicoordinated movement, the task that move the work object ($rob2_obj$) needs to move to the desired position. After that a WaitSyncTask is needed (identity sync3) before the semicoordinated movement can be performed.

6.6 Coordinated synchronized movements

6.6.1 About coordinated synchronized movements

What is coordinated synchronized movements

Several robots can work with the same moving work object.

The positioner or robot that holds the work object and the robots that work with the work object must have synchronized movements. This means that the RAPID task programs, that handle one mechanical unit each, execute their move instructions simultaneously.

Implementation

The synchronized movement mode is started by executing a <code>SyncMoveOn</code> instruction in each task program. The synchronized movement mode is ended by executing a <code>SyncMoveOff</code> instruction in each task program. The number of executed move instruction between <code>SyncMoveOn</code> and <code>SyncMoveOff</code> has to be the same for all task programs.

Advantages

Coordinated synchronized movements usually save cycle time since the robots do not have to wait while the work object is being moved. It also allows robots to cooperate in ways that would otherwise be difficult or impossible to achieve.

Limitations

Coordinated synchronized movements can only be used if you have the RobotWare option MultiMove Coordinated.

6.6.2 Example "SyncArc" with coordinated synchronized movement

6.6.2 Example "SyncArc" with coordinated synchronized movement

Program description

In this example, we want both robots to weld all the way around the object.

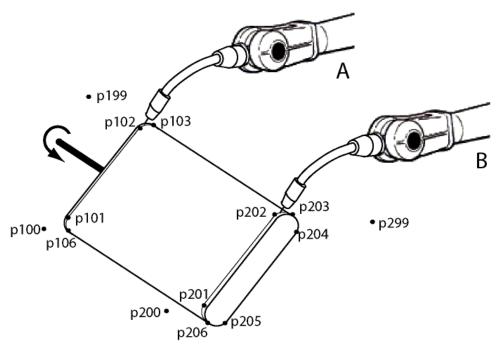

The robot TCPs are programmed to make circular paths relative to the work object. However, since the work object is rotating, the robots will almost stand still while the work object is turning.

Note

To make the example simple and general, ordinary move instructions (e.g. MoveL) are used instead of weld instructions (e.g. ArcL). For more information about arc welding, see *Application manual - Arc and Arc Sensor*.

6.7.1 Corner zones

6.7 Program execution

6.7.1 Corner zones

Corner zones and WaitSyncTask

Corner zones can be used when synchronizing several task programs with WaitSyncTask.

Corner zones and synchronized movements

Stop points must be used both before starting the synchronized movements with SyncMoveOn and before ending it with SyncMoveOff. All other move instructions between SyncMoveOn and SyncMoveOff can, on the other hand, use corner zones.

Dependences between synchronized instructions

In synchronized movements mode, all or none of the simultaneous move instructions must be programmed with corner zones. This means that the move instructions with the same ID must either all have corner zones, or all have stop points. If a move instruction with a corner zone and a move instruction with a stop point are synchronously executed in their respective task program, an error will occur.

Synchronously executed move instructions can have corner zones of different sizes (e.g. one use z10 and one use z50).

Corner zones converted to stop points

A corner zone will become a stop point if the task program has to wait for another task program. This can happen if <code>WaitSyncTask</code> is executed in a corner zone, but one task program reaches this instruction later than the others.

Example with corner zones

Given the RAPID code below, the following will happen:

- If robot1 reaches p11 at approximately the same time as robot2 reaches p21, both robots will be synchronized in corner zones (p11 and p21).
- If robot1 reaches p11 before robot2 reaches p21, p11 will become a stop point.
- If robot2 reaches p21 before robot1 reaches p11, p21 will become a stop point.

Note that both move instructions with corner zones and move instructions with stop points can be used in each task. You just have to make sure that the instructions with the same ID in both task programs are of the same type. The instructions before SyncMoveOn and SyncMoveOff must have stop points.

Part of T_ROB1 task program:

```
MoveL p11, v500, z50, tool1;
WaitSyncTask sync1, all_tasks;
MoveL p12, v500, fine, tool1;
SyncMoveOn sync2, all_tasks;
```

6.7.1 Corner zones *Continued*

```
MoveL p13\ID:=10, v500, z50, tooll \Wobj:=wobj_stn1;
MoveL p14\ID:=20, v500, fine, tooll \Wobj:=wobj_stn1;
SyncMoveOff sync3;
MoveL p15, v500, fine, tool1;
```

Part of T_ROB2 task program:

```
MoveL p21, v500, z50, tool2;
WaitSyncTask syncl, all_tasks;
MoveL p22, v500, fine, tool2;
SyncMoveOn sync2, all_tasks;
MoveL p23\ID:=10, v500, z10, tool2 \WObj:=wobj_stn1;
MoveL p24\ID:=20, v500, fine, tool2 \WObj:=wobj_stn1;
SyncMoveOff sync3;
MoveL p25, v500, fine, tool2;
```

6.7.2 Synchronization behavior

6.7.2 Synchronization behavior

Synchronization point

When one task program reaches a synchronization point, it will wait until all task programs have reached the same synchronization point.

Synchronization points are:

- all WaitSyncTask instructions
- all SyncMoveOn instructions
- all SyncMoveOff instructions
- all move instructions between SyncMoveOn and SyncMoveOff

When one task program reaches a WaitSyncTask, SyncMoveOn or SyncMoveOff instruction, it will wait until all task programs have reached the instruction with the same syncident variable.

All move instructions between SyncMoveOn and SyncMoveOff must use the argument ID. When a task program reaches such a move instruction, it will wait until all task programs have reached the move instruction with the ID argument set to the same value.

Other instructions than movements

All synchronized task programs must execute the same number of move instructions between the SyncMoveOn and SyncMoveOff instructions. This does not affect functions or other instructions than move instructions. It is possible to have any number of functions and instructions that are not move instructions.

Example

In this example both task programs execute two move instructions, but one of the tasks executes other instructions and functions.

Robot 2 will wait and not move to p21 until robot 1 starts to move towards p11.

Since SyncMoveOff is a synchronization point, both tasks will wait for dil to become 1 before executing SyncMoveOff.

Part of T_ROB2 task program:

```
SyncMoveOn sync1, all_tasks;
time := CTime();
Write log, "Synchronization started "\NoNewLine;
Write log, time;
MoveL p11\ID:=10, v500, fine, tool1 \WObj:=wobj_stn1;
Set do1;
MoveC p12, p13\ID:=20, v500, fine, tool1 \WObj:=wobj_stn1;
WaitDI di1, 1;
SyncMoveOff sync2;
```

Part of T_ROB2 task program:

```
SyncMoveOn sync1, all_tasks;
MoveJ p21\ID:=10, v500, fine, tool2 \WObj:=wobj_stn1;
MoveL p22\ID:=20, v500, fine, tool2 \WObj:=wobj_stn1;
SyncMoveOff sync2;
```

6.7.3 Dummy instructions

6.7.3 Dummy instructions

About dummy instructions

The same number of move instructions must be executed between <code>SyncMoveOn</code> and <code>SyncMoveOff</code> in all task programs. If a move instruction is only executed under certain circumstances, the number of move instructions may differ from the other task programs. This can be solved by adding a move instruction to the point where the robot already is (a dummy instruction) for the case where the original move instruction is not executed.

Example with dummy move instructions

In this example, the task program needs to execute two move instructions if di1 is set to 1. If di1 is 0, two move instructions are executed that move the robot to the position where it already is (dummy instructions).

Part of a task program

```
SyncMoveOn sync1, all_tasks;
MoveL pl\ID:=10, v500, fine, tool1 \WObj:=wobj_stn1;
IF dil=1 THEN
! Instructions executed under certain conditions
  MoveL p2\ID:=20, v500, fine, tool1 \WObj:=wobj_stn1;
  MoveL p1\ID:=30, v500, fine, tool1 \WObj:=wobj_stn1;
ELSE
! Add dummy move instructions
  MoveL p1\ID:=20, v500, fine, tool1 \WObj:=wobj_stn1;
  MoveL p1\ID:=30, v500, fine, tool1 \WObj:=wobj_stn1;
  ENDIF
SyncMoveOff sync2;
```

6.7.4 Motion principles

6.7.4 Motion principles

Robot speeds

When the movements of several robots are synchronized, all robots adjust their speed to finish their movements simultaneously. This means that the robot movement that takes the longest time will determine the speed of the other robots.

Example of robot speeds

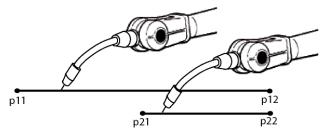

In this example, the distance between p11 and p12 is 1000 mm and the distance between p21 and p22 is 500 mm. When running the code below, robot1 will move 1000 mm at a speed of 100 mm/s. Since this will take 10 seconds, robot2 will move 500 mm in 10 seconds. The speed of robot2 will be 50 mm/s (and not 500 mm/s as programmed).

Part of T_ROB1 task program:

```
MoveJ p11, v1000, fine, tool1;
SyncMoveOn sync1, all_tasks;
MoveL p12\ID:=10, v100, fine, tool1;
```

Part of T_ROB2 task program:

MoveJ p21, v1000, fine, tool2;
SyncMoveOn sync1, all_tasks;
MoveL p22\ID:=10, v500, fine, tool2;

xx0400000907

6.7.5 Modify position

6.7.5 Modify position

About modifying positions

A programmed position can be modified from the FlexPendant, see *Production Window on page 51*.

Modify position in unsynchronized mode

When the movements of the different tasks are unsynchronized, the position of each mechanical unit is modified individually.

Modify position in synchronized movement mode

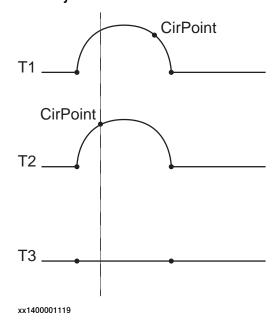

Modifying positions while in synchronized movement mode (when the execution is between a SyncMoveOn and SyncMoveOff instruction) behaves differently depending on if it is done from the Production Window or the Program Editor.

In the Production Window, the position will be modified for all tasks in synchronized movement mode. Circle points cannot be modified from the Production Window while in synchronized movement mode, thus if the marked point is a circle point, the function to modify position from the Production Window will not be enabled. In the Production Window, the position can only be modified for the current move instruction (where the motion pointer is).

In the Program Editor, the position will be modified only for the task program currently open in that editor window.

See also example on circular movement in the description of modifying positions in *Operating manual - IRC5 with FlexPendant*.

Modify circular position in synchronized movement mode

6.7.6 Moving a program pointer

6.7.6 Moving a program pointer

Moving PP in unsynchronized mode

When none of the tasks are in synchronized movement mode, a program pointer in one task can be moved without affecting the other tasks.

Moving PP in synchronized movement mode

If the program pointer is moved for one task, the program pointers for all tasks in synchronized movement mode are lost. This is the case even if the task where the program pointer is moved is not in synchronized movement mode. Even if a task is inactive, moving its program pointer will affect the program pointers of all tasks in synchronized movement mode.

Example

In this example, there are three tasks. Task2 and Task3 are in synchronized movement mode, while Task1 works independently. In this situation, the user taps **Move PP to Main** for Task1.

The program pointers for Task2 and Task3 will be lost.

Task1:	Task2:	Task3:
MoveL p11	MoveL p21	MoveL p31
MoveL p12	SyncMoveOn sync1	SyncMoveOn sync1
MoveJ p13	➡MoveL p22	➡ MoveL p32
MoveL p14	MoveL p23	MoveL p33
➡ MoveL p15	SyncMoveOff sync2;	SyncMoveOff sync2;
xx0500001444		

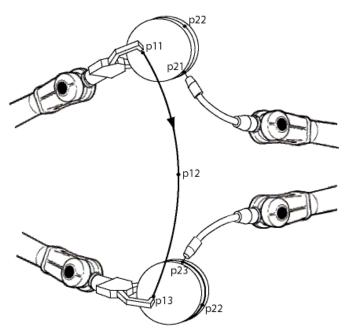

6.7.7 Tool orientation at circular movements

6.7.7 Tool orientation at circular movements

Coordinated circular move instructions

There is a risk for incorrect tool orientation if two coordinated task programs both perform synchronized circular move instructions. If one robot holds a work object that another robot is working on, the circle interpolation affects both robots. The circle point should be reached at the same time for both circle paths to avoid incorrect orientation of the tool.

Example

xx0400000717

If p12 would be in the beginning of its circular path (closer to p11 than p13) and p22 would be in the end of its circular path (closer to p23 than p21) then the tool orientation could become wrong. If p12 and p22 are in the same relative position on the path (percentage of the path length) the tool orientation will remain correct.

Tip

By modifying the position for both robots circle point at the same time, you make sure the tool orientation stays correct. This means that, in the example, you should step through the program and then modify p12 and p22 at the same time.

6.7.8 Applications affected by MultiMove

6.7.8 Applications affected by MultiMove

Collision Detection

If collision is detected for one robot, all robots are stopped. Even if the robots are run individually, all robots behave as if it had collided.

One reason for this behavior is that when a collision is detected, there is a big risk that it was two robots that collided. Another reason is that if one robot stops and another continues, this might cause another collision.

World Zones

A world zone declared in one task program is only valid for the mechanical units that belong to that task. For a world zone to affect all mechanical units, it must be declared in all task programs.

6.8.1 Programming recommendations

6.8 Programming recommendations

6.8.1 Programming recommendations

Declare syncident globally in task

By declaring all variables of the data type syncident globally in the task program, there is no risk of having two syncident with the same name in the same task program.

Do not reuse syncident

A syncident variable is used as an argument for all WaitSyncTask, SyncMoveOn and SyncMoveOff instructions, so that the operator can distinguish which instructions are executed simultaneously in the different task programs. If one syncident variable would be used as argument for more than one instruction per task, that instruction would no longer be uniquely identified. To make sure your program code is understandable, never reuse a syncident variable.

Declaring tools, work objects and payloads

Declaring a variable as TASK PERS will make it persistent in the task program, but not shared between tasks. By declaring tools, work objects and payloads as task persistent, you do not have to keep track of whether the variable name is used in other tasks. If tools, work objects and payloads are declared as TASK PERS, the names do not have to be changed if the program is copied or mirrored to another task.

A work object that is used by several task programs is preferably declared as PERS. A tool can be declared as PERS if a background task needs to read the robot position.

Changing a PERS

A globally declared PERS will keep its value even if a new declaration of the same PERS is loaded. The value of the PERS that was first loaded will be preserved as long as there is any reference to that PERS.

If you want to replace all the task programs with new programs where the values of the PERS is different, remove all task programs first and then load all the new task programs. That way the old value of the PERS will be lost when all declarations of it are removed.

Changing the value of a PERS from the Data Variable view on the FlexPendant and saving the program, will update the PERS in a correct way.

Use SyncMoveUndo

Always use an UNDO handler with a SyncMoveUndo instruction in any procedure that has synchronized movements (i.e. that has a SyncMoveOn instruction).

After a SyncMoveOn instruction, the movements in the task program are synchronized with movements in other task programs. If the program pointer is then manually moved before the SyncMoveOff instruction is executed, the

6.8.1 Programming recommendations Continued

movements will still be synchronized. This can be avoided by having an UNDO handler that includes a SyncMoveUndo instruction.

When the program pointer is manually moved out of a procedure, the UNDO handler for that procedure is called. The <code>SyncMoveUndo</code> instruction will end the synchronization if the movements currently are synchronized. If the movements are not synchronized when the program pointer is moved, <code>SyncMoveUndo</code> will do nothing. It is, in other words, never any disadvantage in using <code>SyncMoveUndo</code>, but very useful if the program pointer is moved.

For more information about UNDO handlers, see *Technical reference manual - RAPID overview*.

Coordinating against a work object

Coordinating against a work object moved by a mechanical unit in another task can be done in two ways:

- All move instructions coordinated with the work object must be executed when the work object is standing still. See Semi coordinated movements on page 63.
- The robot that is coordinated with the work object and the mechanical unit that moves the work object must be in synchronized movement mode. See Coordinated synchronized movements on page 71.

It is not possible to coordinate against a moving work object, controlled from another task, without being in synchronized movement mode.

Common work area

If two robots use the same work area, without being in synchronized movement mode, precautions must be taken to avoid collisions. Make sure that only one of the robots is in the common area at a time by using one of the following:

- WaitSyncTask
- World Zones
- I/O signal

7.1 Error recovery for MultiMove

7 RAPID error recovery

7.1 Error recovery for MultiMove

Error in unsynchronized mode

If an error occurs during unsynchronized mode, it is handled just like in a single robot system. No other task program is affected by the error.

Error in synchronized movement mode

If an error occurs during synchronized movement mode, the task program with the error will stop with an error code, just like in a single robot system. Because of the synchronization, the other tasks will not continue to move. When the error has been resolved the movement can continue in all task programs.

7.2 Simple error recovery example

7.2 Simple error recovery example

About this example

In this example, a division with zero causes an error during synchronized movement mode. Since the error handler can resolve the error without any motion instructions, the error handler does not have to consider the synchronization. The synchronized movement mode is active the whole time and the second move instruction is started for both robots as soon as the error handler has finished. If no other error can occur, the T_HANDLEROB task program does not need to have an error handler.

T_PROCROB task program

```
SyncMoveOn, sync1, motion_tasks;
MoveL p101\ID:=10, v100, z10, gun2 \WObj:=wobj_handlerob;
a:=3;
b:=0;
c:=a/b;
MoveL p102\ID:=20, v100, fine, gun2 \WObj:=wobj_handlerob;
SyncMoveOff sync2;
...
ERROR
   IF ERRNO = ERR_DIVZERO THEN
        b:=1;
        RETRY;
   ENDIF
```

T_HANDLEROB task program

SyncMoveOn, sync1, motion_tasks;
MoveL p201\ID:=10, v100, z10, grip1;
MoveL p202\ID:=20, v100, fine, grip1;
SyncMoveOff sync2;

7.3 Asynchronously raised errors

What is an asynchronously raised error

Asynchronously raised errors can be raised by another instruction than the instruction where the program pointer is. This means that an asynchronous error can be raised while the robot is in the middle of a path movement. For more information about asynchronously raised errors, see *Technical reference manual - RAPID kernel*.

The technique with asynchronously raised errors allows a failing instruction in one task program to raise an error in all other task programs with synchronized movements.

How to raise an asynchronous error

The instruction ProcerrRecovery will raise the error ERR_PATH_STOP and stop the movement for all task programs with synchronized movements.

Asynchronous errors can also be raised by process instructions (e.g. Arcl). These can raise one error code (describing the cause of the error) in the task program where the error occurred, and raise the error ERR_PATH_STOP in the other task programs with synchronized movements.

The task programs without errors

If two task programs run synchronized move instructions and one of them raise an asynchronous error, the movements will stop for both tasks. The task program where nothing went wrong will then get the error ERR_PATH_STOP. This error must be handled by an error handler. The error handler can handle ERR_PATH_STOP by just waiting for the other task to solve its problems and then resume the movements.

By using the instruction StartMoveRetry, the execution will continue when all tasks reach this instruction.

Independent movements in the error handler

If the error handler in one task program needs to execute a move instruction, the synchronization must be suspended first.

The synchronization is automatically suspended by the StorePath instruction. All tasks with synchronized movements must execute a StorePath instruction before the synchronization is turned off and the execution can continue.

The instruction RestoPath will restore synchronization to the mode it had before StorePath. All task programs with synchronized movements must execute the RestoPath instruction in their error handlers before the synchronization is resumed and the execution can continue.

Between the instructions StorePath and RestoPath, the failing task program can move independently to solve its problem. Since RestoPath works as a synchronization point, the other task programs will wait at this point until the problem has been resolved.

If the task program is not in synchronized movements mode, StorePath and RestoPath act just like they do in a single robot system. This means that the same

7.3 Asynchronously raised errors *Continued*

error handler code can handle errors that occur both in synchronized movements mode and unsynchronized mode.

StorePath and RestoPath require the option Path Recovery. For more information about StorePath and RestoPath, see Application manual - Controller software IRC5.

7.4 Example of creating asynchronously raised error

About this example

In this example, a process is started by setting do_myproc to 1. The process is then supervised and the signal di_proc_sup is set to 1 if the process fails.

If a process failure occurs during a robot movement, an interrupt calls a trap routine. The instruction ProcerrRecovery will stop the movement and raise the error ERR_PATH_STOP in all task programs with synchronized movements.

The $T_{HANDLEROB}$ task program must have an error handler that restarts the movement when the error has been resolved in the $T_{PROCROB}$ task program. This only requires one instruction, StartMoveRetry.

T_PROCROB task program

```
VAR intnum proc_sup_int;
PROC main()
 SyncMoveOn, sync1, motion_tasks;
 my_proc_on;
 MoveL p101\ID:=10, v100, z10, gun1 \WObj:=wobj_handlerob;
 MoveL p102\ID:=20, v100, fine, gun1 \WObj:=wobj_handlerob;
 my_proc_off;
 SyncMoveOff sync2;
 ERROR
   IF ERRNO = ERR_PATH_STOP THEN
     my_proc_on;
     StartMoveRetry;
   ENDIF
ENDPROC
TRAP iprocfail
 my_proc_off;
 ProcerrRecovery \SyncLastMoveInst;

7.4 Example of creating asynchronously raised error *Continued*

T_HANDLEROB task program

```
PROC main()
...

SyncMoveOn, sync1, motion_tasks;

MoveL p201\ID:=10, v100, z10, grip1;

MoveL p202\ID:=20, v100, fine, grip1;

SyncMoveOff sync2;
...

ERROR

IF ERRNO = ERR_PATH_STOP THEN

StartMoveRetry;
ENDIF

ENDPROC
```

7.5 Example with movements in error handler

7.5 Example with movements in error handler

About this example

In this example, an asynchronous error can occur that requires the robot to move to another position to resolve the error. The synchronization is suspended by using StorePath in all tasks with synchronized movements, and restored by using RestoPath.

The instruction <code>Arcl</code> is used in this example. This instruction handles the process for arc welding as well as acts as a move instruction. To understand this example, all you need to know is that it is a move instruction (similar to <code>Movel</code>) which can result in asynchronous process errors. For more information about <code>Arcl</code>, see <code>Application manual - Arc and Arc Sensor</code> and <code>Technical reference manual - RAPID Instructions</code>, <code>Functions</code> and <code>Data types</code>.

Note

Note that the T_STN1 task program must have the instructions StorePath and RestoPath, even if there is no code between these instructions. No task program continues to execute its error handler until all task programs execute the StorePath instruction.

T_ROB1 task program

```
SyncMoveOn, sync1, all_tasks;
ArcL p101\ID:=10, v100, seam1, weld1, weave1, z10, gun1
     \WObj:=wobj_stn1;
ERROR
 IF ERRNO=AW_WELD_ERR OR ERRNO=ERR_PATH_STOP THEN
   StorePath;
   IF ERRNO=AW_WELD_ERR THEN
     gun_cleaning;
   ENDIF
   RestoPath;
   StartMoveRetry;
 ENDIF
PROC gun_cleaning()
 VAR robtarget p199;
 p199 := CRobT(\Tool:=gun1 \WObj:=wobj0);
 MoveL pclean, v100, fine, gun1;
 MoveL p199, v100, fine, gun1;
ENDPROC
```

T_ROB2 task program

```
SyncMoveOn, sync1, all_tasks;
```

8.1 How to continue with one or more drive units inactive.

8 Running a subset of a MultiMove system

8.1 How to continue with one or more drive units inactive.

Overview

It is possible to disconnect a drive module and continue working, for example:

- · if a drive module is required elsewhere due to failure or similar.
- for tuning purposes during commissioning, for instance programming one robot at a time while the others are temporarily shut down.

Make sure the application allows work to continue without this drive module, by using the procedure *Continue with the Drive Module Disconnect function on page 95*.

But if one of the following conditions are fulfilled then *Continue with alternative* configuration on page 96.

- · The first alternative fails.
- The limit switches are used on the robot.
- The drive module needs to be moved (e.g. for repair or installation in another cell).

Tip

Sometimes it is necessary to change the program and/or configuration so that the application will work with one less drive module.

Continue with the Drive Module Disconnect function

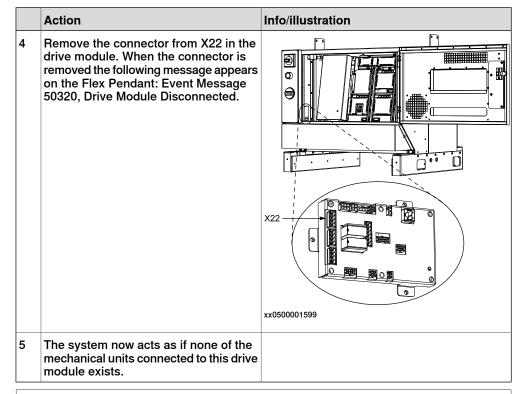

This procedure shows how to let the functional robots continue with their applications without changing the configuration. This requires that the functional robots have no dependencies to the disconnected robot, or additional axes connected to the same drive module.

This is a brief description how to disconnect the drive module, for more detailed information see *Product manual - IRC5*, section *Connections - Connection of the Drive Module Disconnect*.

	Action	Info/illustration
1	Make sure that the system parameter Allow_Drive_Module_Disconnect is set to true.	
2	Switch to manual mode.	
3	Make sure the controller is in Motors Off state.	

8.1 How to continue with one or more drive units inactive.

Continued

Note

Depending on the type of failure, this method may not always succeed. For example if there is an error in the axis computer. In that case, continue with the alternative configuration.

Continue with alternative configuration

This procedure shows how to let the functional robots continue with their applications but with changes in the standard configuration.

	Action	Info/illustration
1	Restart the controller using the restart mode Start Boot Application.	
2	Switch off the controller.	
3	Localize the Ethernet connection cable of the drive module you wish to disconnect. Remove it from the robot communication card in the control module.	See Ethernet connections on page 21.
	Note that the drive module's ethernet cables should be connected in the following order. So that there is no gap in this order: • AXC1 on the Bobot communication card	
	ETHERNET 1 on the Ethernet card	
	ETHERNET 2 on the Ethernet cardETHERNET 3 on the Ethernet card	
4	Locate the safety signal connection cable of the drive module you wish to disconnect. Remove it from the panel board in the control module and replace it with a jumper connector. Move the safety signal connection cables so that there are no gaps in the following order X7, X8, X14 and X17.	See Ethernet connections on page 21.

8.1 How to continue with one or more drive units inactive. Continued

	Action	Info/illustration
5	Switch on the power to the controller.	
6	Select a new robot system that is configured without the disconnected mechanical unit.	
	Note that the configuration has to be in accordance with the connections in step 3.	

8.2 Running a subset in the "Unsync Arc" examples

8.2 Running a subset in the "Unsync Arc" examples

Example with Drive Module Disconnect

In this example the configuration is according to "UnsyncArc", and an error occurs on the process equipment on robot 1. The function Drive Module Disconnect is configured and there are no limit switches on the robots. Robot 2 should continue its work.

	Action	Info/illustration
1	Make sure that the system parameter Allow_Drive_Module_Disconnect is set to true.	
2	Switch to manual mode.	
3	Make sure the controller is in Motors Off state.	
4	Remove the connector from X22 in drive module 1.	X22 xx0500001599
5	The system now acts as if robot 1 does not exist. It is now safe to continue working with robot 2.	

Example without Drive Module Disconnect

In this example limit switches are used on the robots. The configuration is according to "UnsyncArc", and an error occurs on robot 1. Robot 2 should continue its work.

	Action	Info/illustration
1	Restart the controller using the restart mode Start Boot Application.	
2	Switch off the controller.	
3	Remove the Ethernet connection of drive module 1 from the robot communication card in the control module and replace it with a jumper connector. Move the Ethernet connection of drive module 2 from the Ethernet card to the robot communication card.	

8.2 Running a subset in the "Unsync Arc" examples Continued

	Action	Info/illustration
4	Remove the safety signal connection of drive module 1 from X7 on the panel board in the control module. Move the safety signal connection of drive module 2 from X8 to X7. Then push the jumper connector in the X8 connector.	page 21.
5	Switch on the power to the controller.	
6	Select a new robot system that is configured without robot 1.	
	Note that the configuration has to be in accordance with the connections in step 3. I.e. the remaining robot will be referred to as robot 1.	

Tip

The same actions can be taken if the axis computer fails, or other failure that cannot be helped with Drive Module Disconnect.
